Introduction

PowerSafe SBS standby power batteries utilise advanced pure lead, thin plate technology to achieve exceptionally high performance, energy density, reliability and a long, low maintenance service life in a wide range of applications and operating environments. The range includes both top and front terminal designs for easy installation and maintenance on racks, shelves and in cabinets.

PowerSafe SBS combine the benefits of high performance and long life in a cost effective battery solution for tele-communications, UPS, electric utilities and engine starting applications.

PowerSafe SBS batteries are manufactured in ISO 9001 certified factories.

This manual describes the **PowerSafe** SBS product range, physical characteristics and electrical performance, and contains the basic information for the selection, storage, installation, operation and maintenance of **PowerSafe** SBS batteries.

Enersys has earned an international reputation for quality and reliability based on more than 100 years experience in the manufacture of batteries, and is at the forefront of new product design to meet customers increasing power requirements.

PowerSafe SBS batteries are designed using proven gas recombination technology, which removes the need for regular water addition.

The use of gas recombination technology for lead acid batteries has completely changed the concept of standby power. This technology provides the user with the freedom to use lead acid batteries in a wide range of applications. The minimal level of gas production allows battery installation in cabinets or on stands, in offices or near main equipment, thus maximising space utilisation and reducing battery accommodation and maintenance costs.

Range Summary

Monobloc Specifications

Model	Nominal Voltage (V)	C ₈ to 1.75Vpc @ 25°C (77°F)	C ₁₀ to 1.80Vpc @ 20°C (68°F)	Terminal Fastener ¹	Dimensions mm (inches)			Weight kg (lbs)

Notes:

1 M = male stud, F = female thread

2 supplied with wiring harness

3 dimension includes top cover

4 SBSB8, B10, B14, and C11 are available with terminals on the top face or on the front face.

For front terminals add 'FT Adapter' to the model number

5 SBSB8, B10 and B14 are available with a venting manifold, with a spigot at the front or back.

The manifold increases monobloc height by 9mm.

Recombination Technology

How gas recombination works

When a charge current flows through a fully charged conventional lead acid cell, electrolysis of water occurs to produce hydrogen from the negative electrode and oxygen from the positive electrode. This means that water is lost from the cell and regular topping up is needed.

However, evolution of oxygen gas and hydrogen gas does not occur simultaneously, because the efficiency of recharge of the positive electrode is not as good as the negative electrode. This means that oxygen is evolved from the positive plate before hydrogen is evolved from the negative plate.

At the same time that oxygen is evolved from the positive electrode, a substantial amount of highly active spongy lead exists on the negative electrode before it commences hydrogen evolution.

Therefore, provided oxygen can be transported to the negative electrode, conditions are ideal for a rapid reaction between lead and oxygen:

i.e. This oxygen is electrochemically reduced on the negative electrode according to the following scheme,

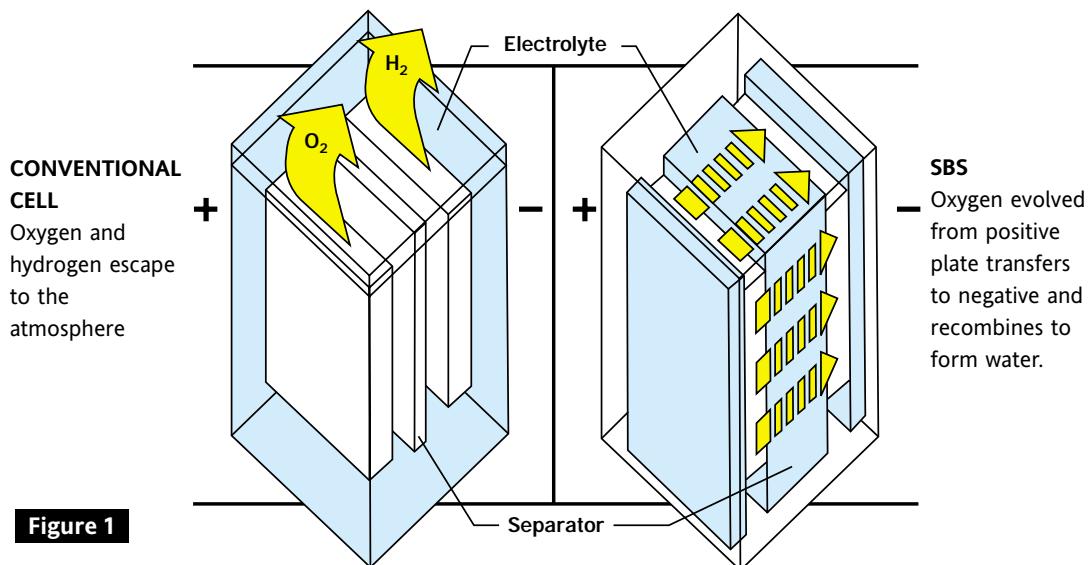

and the final product is water.

The current flowing through the negative electrode drives this reaction instead of hydrogen generation which would occur in a flooded cell.

This process is called gas recombination. If this process was 100% efficient no water would be lost from the cell. By careful design of the constituents within the cell, gas recombination up to 99% is achieved.

Principle of the Oxygen Reduction Cycle

Recombination efficiency

Recombination efficiency is determined under specific conditions by measuring the volume of hydrogen emitted from the battery and converting this into its ampere hour equivalent. This equivalent value is then subtracted from the total ampere hours taken by the battery during the test period, and the remainder is the battery's recombination efficiency and is usually expressed as a percentage.

As recombination is never 100%, some hydrogen gas is emitted from SBS cells and batteries through the self-regulating valve. The volume of gas emitted is very small and for all practical purposes may be ignored.

Construction

1 Terminal Posts

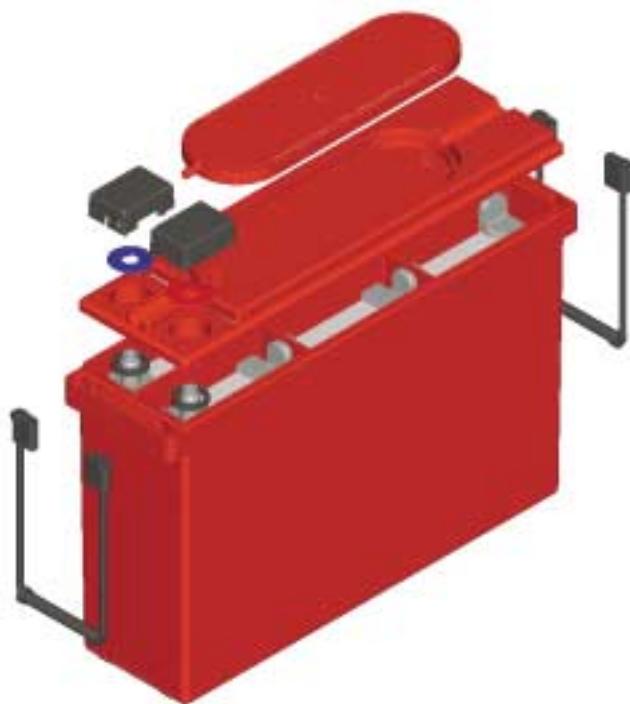

High conductivity post for high rate discharge.

2 Pillar Seal

Compressed rubber grommet for superior integrity.

3 Container and Lid

Heat-sealed for maximum strength. SBS cases are made of ABS and SBS J are made of Noryl. Both materials are flame retardant (UL94 V-0).

4 One Way Valve

Ensures no oxygen can enter the cell. Optional remote venting systems are available. Vent adapters and a neoprene tubing system transport gases outside the battery compartment. This is only a safety measure because, under normal operating conditions, gas emission is virtually negligible.

5 Pure Lead Plates

Advanced thin grid technology and high purity materials for high performance, efficient charging and long life.

6 Negative Plates

Active material is balanced against the positive for optimum performance and recombination efficiency.

7 Flame Arrestor

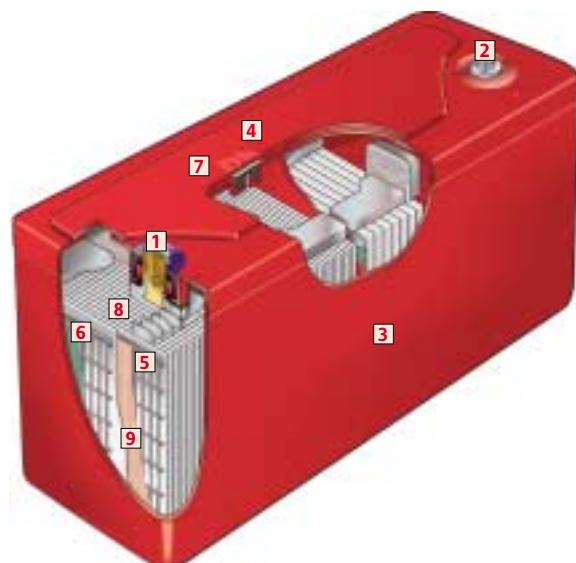

The valve retaining disc also functions as a flame Arrestor to prevent ingress of a spark or flame.

8 Separators

Separator material is resilient to scuffs and tears to minimise risk of internal shorts caused by a damaged separator.

9 Electrolyte

Medical grade dilute sulphuric acid is absorbed into separator material.

Features and Benefits

Design Life

- High purity materials give SBS batteries a long float life. On constant voltage float charge systems the design life expectancy is 10+ years at 25°C/77°F and 15+ years at 20°C/68°F.

Energy Density

- The advanced thin plate pure lead technology promotes exceptionally efficient utilisation of the active materials. SBS energy density is typically 12 to 30 % higher than conventional lead calcium VRLA batteries.

Operating Temperature

- The recommended operating temperature range for optimum life and performance is 20°C/68°F to 25°C/77°F.
- However, SBS can be operated in the temperature range -40°C/-40°F to 50°C/122°F, and by using the optional metal jacket the maximum operating temperature of the SBS J types is increased to 80°C/176°F.
- Operation at higher or lower temperature will effect battery life or performance respectively:

-40°C/-40°F to 19°C/66°F	20°C/68°F to 25°C/77°F	26°C/78°F to 50°C/122°F
Lower capacity	Optimum life and performance	Shorter life

Transportation

- SBS products are classified as “nonspillable wet electric storage batteries” and may be shipped by air or ground transportation without restriction.
- The batteries, their shipping container and external packaging must be labelled “nonspillable” or “nonspillable battery”.
- SBS batteries are in compliance with:
 - USA 49 Code of Federal Regulations section DOT 173.159*
 - ICAO/IATA Packaging Instruction 806 and Special Provision A67*
 - IMDG UN No 2800 Class 8 Exempt when securely packaged and protected against short circuits.*

Orientation

The batteries can be installed in any orientation except upside down (vents on the bottom).

Terminal Position

- The SBS range comprises of both top and front terminal models, and JIS and unique SBS container sizes for maximum battery layout flexibility.

Low Gas Emission and Remote venting

- Under normal operating conditions, gas emission is virtually negligible. On SBS15-60, SBS J and front terminal models optional venting systems are available to vent gas outside the battery compartment. The remote venting system allows batteries to be installed in applications where there is little ventilation.

Battery capacity is affected by the discharge rate, end voltage, temperature and age.

Battery sizing calculations should include factors for temperature and loss of capacity over life. A battery usually is determined to have reached end of life when its capacity has fallen to 80% of its rated capacity.

Strings of the same SBS batteries can be connected in parallel to obtain higher capacities.

Telecom Applications

In general, telecom applications are a constant power or constant current load for a specified period, to a specified end voltage. The appropriate battery model can be selected by referring to the Discharge Tables.

EXAMPLE 1

The following information is needed:

- Nominal system voltage
- Minimum system voltage
- Load (constant current or constant power)
- Backup time
- Temperature range

A nominal 48V system requires a constant current of 9 Amps for 4 hours to a minimum of 42V at a minimum operating temperature of 20°C/68°F.

Step 1. Number of cells = nominal system voltage divided by nominal cell voltage:

$$48V/2V = 24 \text{ cells}$$

Step 2. Cell end voltage = minimum system voltage divided by the number of cells:

$$42V/24 \text{ cells} = 1.75 \text{ volts per cell}$$

Step 3. Correct load for temperature and ageing:

Temperature factor = 1/Factor from Temperature

Correction Chart = $1/0.978 = 1.022$

Ageing factor = $100/80 = 1.25$

$9 \text{ amps} \times \text{temperature factor} \times \text{ageing factor} =$

$$9 \text{ amps} \times 1.022 \times 1.25 = 11.5 \text{ Amps}$$

Step 4. Refer to the constant current discharge table for an end voltage of 1.75 Vpc, and in the 4 hour column find the model that will provide the load current. In this example an SBS60 will provide 11.7 amps/ 4 Hrs/1.75Vpc SBS60 is a 12V six cell monobloc, so 4 blocs are required for a 48V battery.

UPS Applications

In general, UPS systems are rated in kVA, (kilo Volt Amperes). This is a multiplication of the output voltage in Kilo Volts and output current in amperes. The kVA rating is always an AC rating. The kVA rating may be converted to kW by simply multiplying the kVA by the Power Factor (PF).

$$\text{kW Rating of UPS} = (\text{kVA of UPS}) \times (\text{PF of UPS})$$

$$\text{kW Rating of UPS Battery} = \frac{\text{kVA} \times \text{PF}}{\text{Inverter Efficiency}}$$

EXAMPLE 2

This first example covers a basic sizing procedure with no power factor or efficiency involvement. This procedure details only the fundamental steps required.

In an example such as this the following information is needed as a minimum requirement:

- (i) system kilowatts
- (ii) required autonomy (run time)
- (iii) minimum DC voltage
- (iv) maximum DC voltage

If the load is given in kVA, then the PF and inverter efficiency values must also be known.

Therefore, for a UPS requiring the following autonomy,

Battery kW Rating: 10

Battery nominal voltage: 120

Battery end voltage: 1.67 Vpc

Battery run time: 10 minutes

Battery Sizing

Step 1. Number of cells needed per string
= 120 (nom.volt) /2 (nominal cell voltage)
= 60 cells

Step 2. Watts per cell required to support the load
= 10,000 (Watts) /60 (cells)
= 166.67 Watts per cell

Step 3. Refer to the constant power discharge tables for an end voltage of 1.67 Vpc, and in the 10 minute column find the model that can support a load of 166.67 Watts per cell.

SBS40 will provide 205 Wpc for 10 minutes.

Step 4. Calculate the number of blocs required to make up the battery string. The number of blocs
= System Nominal Voltage/Bloc Nominal Voltage
= 120V/12V = 10 blocs.

Therefore 10 SBS40 blocs are required to make up the battery string

EXAMPLE 3

This example is slightly more complex in that it takes into account both the power factor and the system efficiency.

UPS kVA rating: 12.0

Inverter power factor: 0.80

Inverter efficiency: 85%

Battery nominal voltage: 120

Battery end-voltage: 1.67 Vpc

Battery run time: 15 minutes

Step 1. Total power required from battery = $\frac{\text{kVA} \times \text{PF}}{\text{Inverter Efficiency}}$
= $\frac{12.000(\text{kVA}) \times 0.80(\text{PF})}{0.85 (\text{Inv.eff})}$
= 11.294 kW

Step 2. Watts per cell required to support the load
= $\frac{\text{Total power required from battery}}{\text{no. of cells}}$

$$= \frac{11.294 (\text{kW})}{60 (\text{cells})}$$

= 188.2 Watts per cell

Step 3. Refer to the constant power discharge tables for an end voltage of 1.67 Vpc, and in the 15 minute column find the model that can support a load of 188.2 Watts per cell.

SBS60 will provide 206 Wpc for 15 minutes.

Step 4. Calculate the number of blocs required to make up the battery string. The number of blocs
= System Nominal Voltage/Bloc Nominal Voltage
= 120V/12V = 10 blocs.

Therefore 10 SBS60 blocs are required to make up the battery string

With both of these examples, by reference to the discharge tables, it is possible to use a parallel string system with smaller SBS models.

These are basic examples. For split duty regimes and other more complex sizings, contact our sales department.

¹ Figures apply to all products

² REPV = Recommended End Point Voltage (the on-load voltage at which it is recommended to disconnect the battery from any load)

Performance Information

End of Discharge Voltage

The voltage point to which a battery can be discharged is a function of the discharge rate. The recommended end voltage point (REPV) is the voltage at which a battery should be disconnected from the load.

Discharging the battery below the REPV or leaving the battery connected to a load in a discharged state will “overdischarge” the battery and may impair its ability to accept charge. In “overdischarge” conditions the sulphuric acid electrolyte can be depleted of sulphate ions and become essentially water. A lack of sulphate ions as charge conductors will cause the cell impedance to appear high and little charge current to flow. Longer charge time or alteration of the charge voltage may be required before normal charging can be resumed.

In a severe “overdischarge” condition, the lead sulphate present on the plate surfaces can go into solution in the electrolyte. Upon recharge, the water and sulphate ion in the lead sulphate convert to sulphuric acid. This can result in dendritic shorts between plates leading to cell failure.

Disconnecting the battery from the load when the REPV is reached will eliminate the risk of overdischarge. The battery must be re-connected and put on charge as soon as mains power is restored.

Note: When the load is removed from the battery, its voltage will increase, up to approximately 12V. Because of this phenomenon some hysteresis must be designed into the battery disconnect circuitry so that the load is not continuously reapplied to the battery as the battery voltage recovers.

The battery disconnect circuitry must not itself impose any residual load on the battery after disconnection.

Storage

Batteries lose capacity when standing on open-circuit because of parasitic chemical reactions. SBS self-discharge rate is very low because of the high purity of the grid lead and electrolyte.

Batteries should be stored in a cool, dry area.

High temperature increases the rate of self-discharge and reduces storage life.

Figure 2 shows the relationship between open-circuit voltage and storage time at five temperatures.

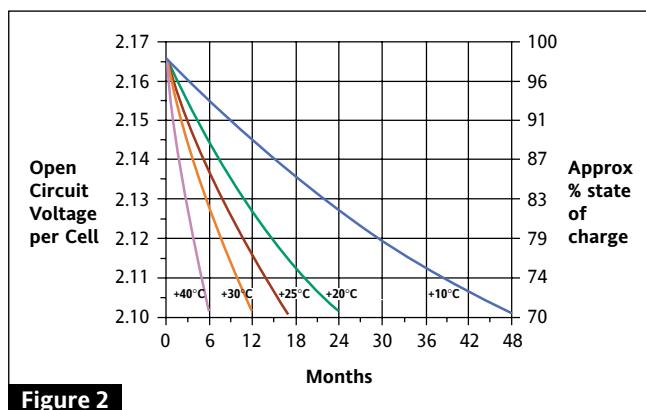

Figure 2

The maximum storage times before a freshening charge is required and recommended open circuit voltage (OCV) audit intervals are:

Temperature °C	Storage (Months)	OCV Audit (months)
10	48	6
15	34	6
20	24	4
25	17	4
30	12	3
35	8.5	2
40	6	2

Monoblocs must be given a freshening charge when bloc voltages approach the equivalent of 2.10 Volts per cell or when the maximum storage time is reached, whichever occurs first.

Freshening Charge

Charge the monoblocs, or strings at a constant voltage equivalent to 2.27 to 2.4 Volts per cell with 10% of C₁₀ current available, for 24 hours.

Installation

Warning

SBS monoblocs are supplied in a charged condition, and are capable of extremely high short circuit currents. Take care to avoid short-circuiting terminals of opposite polarity.

Unpacking

Open the shipping containers and check the contents for damage and against the packing list. Immediately inform the Enersys sales department of any damaged or missing items.

Battery Location

Batteries can be installed on racks, shelves or in cabinets. The floor must be capable of supporting the combined weight of the battery, housing, accessories and cables.

Monobloc Connection

Each battery is supplied with an instruction sheet or manual.

The positive terminal on each monobloc is identified by a "+" sign and/or a red collar round the terminal. Install the monoblocs in accordance with the instructions and layout drawing. Check that the correct terminal orientation and positive/negative polarity sequence is maintained throughout the battery string.

Connect the blocs together with the connectors and fasteners provided. The fastener torque values are:

Model(s)	Fastener	Torque
SBS8	M4	1.0 Nm / 9 in lbs
SBS15–60	M6	3.9 Nm / 35 in lbs
SBS110–390	M8	5.0 Nm / 44 in lbs
SBS J13–70	M6	6.8 Nm / 60 in lbs
SBSB8–14	M8	5 Nm / 44 in lbs
SBSC11	M8	5 Nm / 44 in lbs

Place the insulating covers in position immediately after tightening the fasteners.

The main battery cables are now ready to be connected to the system.

Site Acceptance Tests

Before conducting a capacity discharge or fully loaded duty cycle test the battery must be given a commissioning charge. The commissioning charge shall consist of 7 continuous days of float charge at the recommended float voltage with no load connected to the battery, see Charging, page 19.

Ventilation

During normal charging conditions the volume of hydrogen emitted from a SBS battery is virtually negligible, and will normally dissipate rapidly into the atmosphere. To comply with the requirements of EN 50272, Part 2, the battery room, or cabinet must have sufficient air circulation to limit the accumulation of hydrogen gas to a maximum of 1% by volume, when the battery is being charged at the equivalent of 2.40 volts per cell.

Optional remote venting systems are available to vent gases outside the battery compartment.

SBS typical hydrogen evolution rates on stabilised float at 25°C/77°F are:

Volts/Cell	Hydrogen Evolution = ml/hour/bloc		
	2.27 Vpc	2.40 Vpc	2.45 Vpc
SBS8	0.7	3.6	6.9
SBS15	1.4	7.3	14

SBSC11	5.6	29.6	56.2

Battery Housings

Battery housings should provide at least 150mm / 6 inches of free space above top terminal batteries for installation and maintenance access.

Telecom Batteries

SBS batteries usually are installed on shelves or in cabinets supplied by the equipment manufacturer.

If the equipment does not include the battery housing, Enersys can provide a variety of shelves and racks. Consult a Enersys representative for details.

Racks

For higher voltage battery strings, a variety of stepped and tiered racks are available. Rack length can be customised for specific battery layouts. Consult a Enersys representative for details.

- *Non-seismic* - Racks, shelves and cabinets must be assembled and installed in accordance with the instructions provided with the equipment.
- *Seismic* - Because of the variations in building design and construction materials and methods, it is the responsibility of the battery installer to ensure seismic battery housings are anchored to the floor with the appropriate type and size of anchor bolts and in accordance with applicable building codes.

The completed battery and housing assembly and anchoring method must provide for a self supporting structure that can withstand overturning moments caused by earthquakes without auxiliary support or bracing.

Earthing

Batteries and housings can be earthed or isolated. The earthing or isolation materials and methods will depend on the application, voltage, location and type of battery housing.

The system specification should include the most appropriate combination of earthing and isolation methods for the safety of the installation, operation and maintenance personnel, system integrity and compliance with applicable building and safety codes.

It is the responsibility of the battery installer to ensure that the battery and housing is earthed or isolated in compliance with the system specification.

Voltage Setting

SBS are designed for continuous float operation on constant voltage chargers. Constant voltage charging is the safest, most efficient and recommended method of charging VRLA batteries.

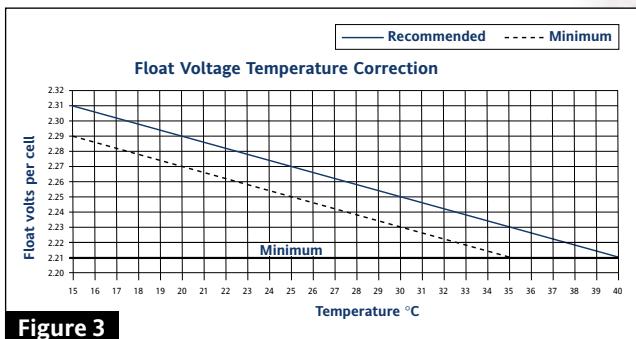

The recommended float voltage setting is 2.27 volts per cell at 25°C/77°F. Therefore the system voltage setting equals the number of cells in series x 2.27Vpc.

Battery life and charging characteristics are affected by temperature. Optimum battery life will be achieved when the battery is operating between 20°C/68°F to 25°C/77°F.

Battery life is reduced by 50% for every 10°C/18°F increase in temperature. Float voltage compensation reduces the charging current as battery temperature increases, and partially negates the adverse effect of high temperature.

The recommended float voltage temperature compensation is:

- $2.27\text{Vpc} + 0.004 \text{ mV per cell per } ^\circ\text{C}/1.8^\circ\text{F}$ below 25°C/77°F
- $2.27\text{Vpc} - 0.004 \text{ mV per cell per } ^\circ\text{C}/1.8^\circ\text{F}$ above 25°C/77°F

The battery and ambient temperatures can be significantly different. Batteries have a large thermal mass, and there is a substantial time lag between changes in ambient and battery temperature.

Thermal sensors must register battery temperature, not ambient temperature. As a rule, sensors should be placed in the following positions:

- Front terminal models - in the centre of the side wall of a bloc, in the middle of the string
- Top terminal models - attached by a ring terminal to the terminal of a bloc in the middle of a string

Sensors on the side of blocs should be insulated from ambient temperature.

Temperature compensation is capped at 40°C/104°F, at higher temperature the compensated voltage approaches the battery open circuit voltage and there would be insufficient over voltage to keep the battery in a fully charged condition.

Charging Current

There is no limit on the charging current provided the float voltage is set at the recommended value as the battery itself will regulate the current, accepting only as much as is required to reach float voltage.

Recharge time is a function of the charging current.

To recharge in an acceptable time it is recommended that the current output of the charger should be equal to the standing load plus 0.1C₈ to 0.4C₈.

Typical recharge times are shown in Figure 4.

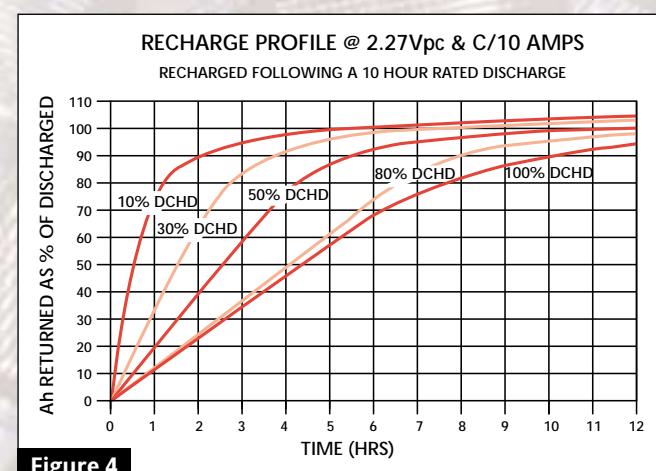

Figure 4

Charging

Fast Charging

"Fast" charge techniques are best suited for frequent discharge or cyclic applications.

For applications requiring a faster recharge, a potential of 2.38 volts per cell at 25°C/77°F can be applied to the battery. This will achieve a faster recharge. However, it is recommended that this higher potential only be applied until the charging current remains constant for a period of two hours. The voltage should then be set at the recommended float voltage.

Charging at a high potential for extended periods may warm the battery, increase grid corrosion and reduce the life of the battery.

Voltage temperature compensation is applicable to "fast" charging.

Constant Current Charging

Only constant voltage charging is recommended. However, constant current charging is an acceptable method of charging SBS batteries provided safeguards are taken to avoid overcharge.

- The maximum recommended charging current is $0.05C_8$.
- It is important to know how many ampere-hours (Amps x hours) are removed from the battery on discharge.
- The duration of a constant current recharge should be set to return 105% of the capacity removed during the discharge.

For example: an SBS60 is rated at 51 Ah/C₈/1.75Vpc/25°C
Maximum charging current = $51 \times 0.05 = 2.55$ amps
If the battery is fully discharged, the recharge time = $51 \text{ Ah} \times 1.05 / 2.55 = 21$ hours.
Therefore, the battery should be at 2.55 amps for 21 hours to bring it to a fully charged condition.

- Continuing the charge for an extended period will overcharge the battery.

Ripple

Voltage Ripple

Is normally seen as a cyclic variation of the DC charging voltage, usually at twice the mains supply frequency, i.e. 100 Hz for a 50 Hz supply, or twice the switching frequency with switch mode rectifiers.

Under steady state conditions the charger output voltage, with the load, but not the battery connected, should not vary by more than $\pm 1\%$ over the range of 5 to 100% of the charger's rated output current.

With the battery disconnected, the voltage ripple, the summation of the effects of load and input supply variations, on the DC charging voltage should not vary by more than 2% of the nominal value.

AC Current Ripple

All AC ripple currents cause internal heating of the battery due to the $I_{rms}^2 \times R_{internal\ losses}$. The heat generated causes an increase in the battery's self-discharge rate resulting in increased float currents and can in marginal - high ambient temperature - situations lead to thermal runaway.

During recharge or float charge the AC current into a battery should have a positive value as shown in the following graph (Figure 5). Ripple current must not exceed 10% RMS of the batteries nominal C₈ capacity and must never be a negative value.

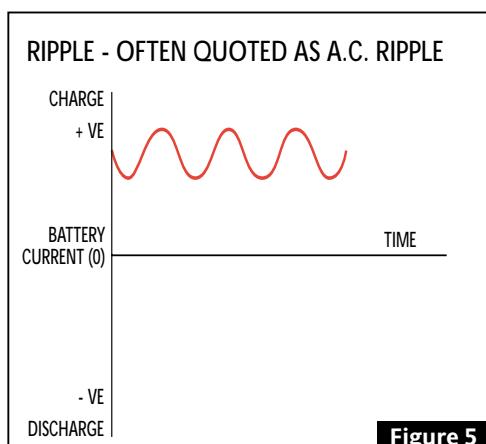

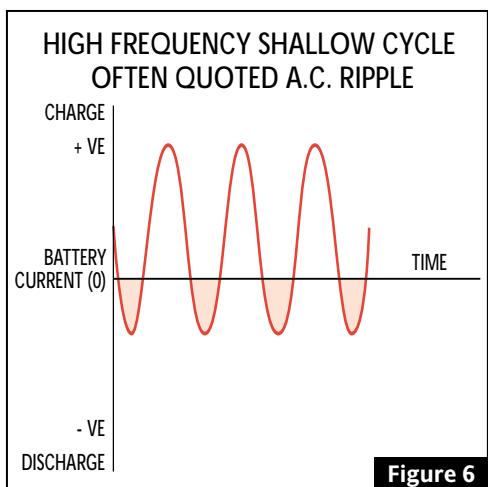

Figure 5

The output of some UPS inverter systems can produce the type of wave form shown in Figure 6. This will subject the battery to high frequency discharge, and the battery will slowly lose capacity and may sustain irreparable damage.

Cycling

SBS are designed to meet or exceed the cyclic requirements of telecommunications standards, and can be cycled at charge voltages between 2.27 and 2.40 Volts per cell.

SBS cyclic performance and life in an application will be affected by the following factors:

- Discharge rate
- Depth of discharge
- Recharge voltage, current and time
- Operating temperature

There are too many variables to be taken into consideration to make non-specific claims for cyclic life. For advice on the most suitable SBS cyclic battery please provide details of the application to Enersys.

Maintenance

SBS batteries are low maintenance items compared with flooded batteries. Nevertheless, some maintenance is necessary to ensure the battery is in good condition.

Installation and Maintenance activities should be recorded. Record sheets are included in the Operating and maintenance manual provided with the battery. A sample record sheet is at the end of this section.

Below is a suggested maintenance routine. However, the frequency of inspection and maintenance procedures may vary depending on the criticality, number and location of installations, equipment and commercial considerations.

Records

It is important to keep a written record of a battery's service life. The record is an aid in fault diagnosis and predicting end of life. The record sheet should be kept with the battery so its operating characteristics and service history is available to anyone that works on it. Enersys may require the record if a warranty claim is made.

Record sheets should be designed so that "trends" and "sudden deviations" are easily noticeable.

Trend Data - can be helpful in predicting end of battery life so that battery replacement can be scheduled and sudden or catastrophic failures can be avoided.

Sudden Deviations - in bloc or string readings should be investigated, it may be indicative of a cell or charger defect.

Readings

Every three months measure and record:

- String voltage
- Bloc voltage
- Charger voltage
- Charging current
- Battery and ambient temperatures

String Voltage Readings

String voltage must be measured at the battery's terminal. If applicable, float voltage temperature compensation must be taken into consideration.

- String voltage = Number of Cells in Series x Float Voltage Per Cell
- Correct float voltage will maintain the battery in a fully charged condition, recharge in an acceptable time and achieve optimum life.
- High float voltage will increase the rate of positive grid corrosion, gassing, risk of thermal runaway and reduce battery life.
- Low float voltage will extend recharge time, not replace internal losses and may cause degradation of the negative plate leading to gradual permanent loss of capacity.

A discrepancy between the voltage measured at the battery terminals and the charger voltmeter must be investigated.

If necessary, adjust the float voltage to the correct value.

Bloc Voltage Readings

Bloc voltages may vary within a string, but individual stabilised bloc voltages should be reasonably constant. The individual blocs should be within ±5% of the mean.

A sudden significant, or a small but continuous, deviation from the bloc's stabilised voltage should be investigated.

Inspection

Inspect the blocs for dust, damage, leaks, loose or corroded connectors. If a bloc or battery needs cleaning it should be isolated and cleaned with a damp soft cloth.

Disposal

SBS batteries are recyclable. Scrap batteries must be sent to a licensed recycling facility for disposal.

Scrap batteries must be packaged, transported and recycled in accordance with local and national regulations.

A list of licensed recyclers and additional information on battery disposal can be found on the web site:
www.recycle.net/battery.

Maintenance

Battery Installation and Maintenance Record Sheet

Installed by: _____ Date: _____ Battery Type: _____ Site: _____
